```
-----------------------------------
Apache Hardening Service Security:
``````````````````````````````````
1) Hide Apache Version and OS Information:
``````````````````````````````````````````
# vim /etc/httpd/conf/httpd.conf

ServerTokens Prod
ServerSignature Off

NOTE: ServerSignature will remove the version information from the page generated
like 403, 404, 502 etc...

# systemctl restart httpd
++++++++++++++++++++++++
If we want to remove information about PHP, we have to edit the php.ini configuration file. The
directive should be changed from:

expose_php = On

to:

expose_php = Off

2) Disable Directory Listing:
`````````````````````````````
<Directory /home/sniper/public_html/lol>
        Options -Indexes
</Directory>

3) Restrict Access to Sensitive Directories:
````````````````````````````````````````````
<VirtualHost *:80>
    ServerName example.com
    DocumentRoot /var/www/html

    # Other virtual host settings

    <Directory /var/www/html/sensitive_directory>
        Require all denied
    </Directory>
</VirtualHost>

EXAMPLE:
````````
    <Directory /var/www/html/sensitive_directory>
        Order allow,deny
        Allow from ???
    </Directory>
```
```
